A Breath Activated Switching Mechanism for the Electric Powered Prehension Orthosis: Design and Fabrication

INTRODUCTION

A person with quadriplegia, paralysis of all four limbs caused by lesions at high levels of the spinal cord, has extremely complex needs for rehabilitation care. Quadriplegia has a devastating effect on a person's entire life. Even after successful rehabilitation, the formerly independent person intermittently requires the help of an attendant for many activities of daily living and activities required for gainful employment or for attending school.

Because attendant care is the single greatest cost of living, exceeding even medical cost, for a person with quadriplegia, any intervention that improves independent function of a person with quadriplegia enough to reduce this need for attendant care should be investigated. Furthermore, if a device can allow a quadriplegic person to be gainfully employed, the cost to the individual and to society would be further reduced and the person with quadriplegia could be much more self-reliant.

Our early experience indicates that the use of a Breath Activated Switching Mechanism (B.A.S.M.), rather than the switching mechanisms that are now available, may improve the ability of quadriplegic persons to use the electric powered prehension orthoses that are already available. Furthermore, the extent of this improvement may be significant enough to reduce the need for attendant care and to improve the outlook for gainful employment.

Certain types of adaptive aides have been used to substitute for hand function. Some quadriplegic persons have received automated devices, such as environmental control units (ECU) that provide some measure of independence in such activities as the turning on and off of lights and appliances and answering the telephone (Figure 1). While E.C.U.s provide much assistance to the home bound quadriplegic person, they cannot be moved from place to place. The user requires attendant care for most activities outside the home. Furthermore, automated devices do not give the user the personal satisfaction of using the hand in a “normal way.”

Mouthsticks have been used to extend the functional independence of those with...
Environmental control units (ECU) provide some measurement of independence, such as the turning on and off of lights and appliances and answering the telephone. The wrist-driven fin­ger prehension orthosis.

4 The most severe paralysis of the upper extremities. However, they do not permit independence from an attendant and are often poorly accepted by patients who have enough upper extremity strength to move their hands about.

Most people with quadriplegia retain some use of the upper extremities. The person with C-5 level quadriplegia (in this paper, the level of lesion is named by the lowest normally functioning spinal segmental level), the most common level of traumatic quadriplegia, is left with no function in the wrist and hand complex, but has preservation of flexion at the elbow and some ability to elevate and move the shoulder joint. This person can move the hand to different positions in space; but has no grasp-release function of the hand. Some C-4 level quadriplegic persons have enough strength of the shoulder girdle and elbow to move the hand about; but, like the C-5 quadriplegic person, they also have no grasp-release function of the wrist or hand. Many persons with C-6 level quadriplegia, the next most common level, have insufficient wrist extension power to be able to use a wrist driven finger prehension orthosis (Figure 2).

Most of the people will be fitted with a static orthosis (Figure 3). A static orthosis, when properly designed and fitted, will...
allow the user to do some activities of daily living (ADL).

However, it is impossible for the user to accomplish many of these tasks, or to switch from one activity to another, without the assistance of another person.

If prehension and release could be provided to a quadriplegic person who is able to move his or her hand to different positions in space, most of the functional tasks needed for employment at a desk job, performing school work, activities of daily living, and participating in social activities could be accomplished without any need for an attendant. A few people have been fitted with an electric powered prehension orthosis (E.P.P.O.) that provides a "three-jaw-chuck" type finger prehension (Figure 4). The E.P.P.O. has been perhaps the most promising development to improve function for quadriplegic persons who are appropriate candidates. However, the usefulness of the E.P.P.O. has been limited by the awkwardness of the switching mechanisms normally supplied with these orthoses. These mechanisms are normally pull or butterfly-type switches that are operated by movements of the shoulders or the contralateral limb, respectively (Figure 5).

Many users cannot achieve a good functional result with an E.P.P.O. because these switches do not allow them to fully concentrate on the task at hand. The major problems associated with these switching mechanisms are due to the users' impaired sensation, as well as their limited and poorly controlled movements. The butterfly switch can be especially difficult to use when visual input is the only available position sense. The user must constantly shift his/her attention from the task at hand to the operation of the switch by the other arm (assuming a functional contralateral limb). The pull-type switch requires the user to have very finely coordinated movement because the three modes—open, close, and off—are in close sequence. Lack of fine control or maladjustment may cause the orthosis to react improperly.

Many attempts have been made to solve such switching problems, because these problems can make the simplest task frustrating, unnecessarily fatiguing, or impossible. A switching problem can make the difference between acceptance and rejection of an otherwise functional orthosis. For example, as far back as the early 1950's, surface E.M.G. electrodes have been used to operate switches on orthoses and pros-
DESIGN AND DEVELPOMENT OF THE BREATH ACTIVATED SWITCHING MECHANISM (B.A.S.M.)

After consulting rehabilitation engineers and trying out several designs, a schematic diagram for an interface control was drawn up for a "breath activated switching mechanism" using two Fairchild Ultralow differential pressure sensors, Basic Model PSF 100A, manufactured by Dumont (Figure 7). This switch senses as little as .002 PSI of air pressure (Figure 8).

Figure 8. (right) The switch senses as little as .002 PSI of air pressure.
The following information is taken by permission from Dumont's printed form #PSF 782/37371PO.

**SPECIFICATION:**

**Mechanical**

- **Switch Type**—SPST, Normally Open, Double Break
- **Switching Medium**—Air
- **Actuation Pressure**—Refer to table of standard actuation ranges for PSF 100A models
- **Proof Pressure**—PSF 100A 100A-1.5, PSF 100A-3 8 PSIG, “C” Series 15 PSIG
- **Mechanical Life**—More than 10 million cycles
- **Weight**—Less than 10 grams
- **Shock and Vibration**—At zero or above actuation pressure, will not make or break at 50G’s shock. Will not make or break at 10G’s shock, 50 to 2000 Hz vibration.

**Physical**

- **Mounting**—Eyeleted for No. 2 screws
- **Case Material**—Polycarbonate
- **Contact Materials**—Gold inlay on phospher bronze

**Electrical Connections**—Terminals—3/16” male tab-type, for use with 3/16” female quick disconnects (ref. AMP 609722LP or equivalent)

- **Pressure Ports**—Two 3/16” diameter barbed ports for use with 5/32” ID tubing. Suggested materials: Silicone, Neoprene, Polyurethane

**Electrical**

- **Current Rating**—10 MA, resistive, DC nominal
- **Operating Voltage**—AC/DC 30V or less with resistive load, 120 VAC neon lamp load (Use with SRF 100B Solid State Relay for higher loads).

A prototype B.A.S.M. was fabricated using two (2) PSF 100A sensors, one (1) RCA integrated circuit #SK-9094-2014 Darlington Array, CMOS/POMS interface, and two (2) Archer’s subminiature PC relays #275-243. These were attached to a basic integrated circuit board (Figure 10).

* Schematic by Calvin P. Franke, Engineering Technician III, Department of Physiology, The University of Texas Health Science Center at San Antonio.
The B.A.S.M. was connected to the E.P.P.O. and fitted for use. The only problem with this B.A.S.M. was occasional failure of the hand wired integrated circuit boards due to faulty soldering techniques. The wired circuit board has been replaced with a custom printed board, which is now in use in nine E.P.P.O.s. No failures have occurred since the printed circuit boards were introduced (Figure 11).

**FABRICATION OF THE BREATH ACTIVATED SWITCHING MECHANISM**

This section consists of detailed instructions for fabrication of a breath activated switching mechanism.

A) Attach the two (2) PSF 100A sensors, one (1) RCA integrated circuit #SK-9094-2014, and two (2) Archer subminiature relays #275-243 to the printed circuit board** as shown in Figure 12.

B) After the components are attached to the circuit board, the following parts are
used to adapt the B.A.S.M. to the E.P.P.O.:
1. Two pieces $\frac{5}{32}$" transparent plastic tubing 5cm. long.
2. One piece $\frac{5}{32}$" transparent plastic tubing 90cm. long.
3. One piece "T" connector $\frac{5}{32}$".
(Note: The above items are available at many pet stores.)
4. One piece 5cm. wide cotton webbing about 30cm. long.
5. One piece 5cm. wide hook and adhesive-backed loop Velcro® about 5cm. long.
6. One piece $\frac{1}{2}$" adhesive-backed loop Velcro® 5cm. long.
7. One piece $\frac{1}{2}$" adhesive-backed hook Velcro® 5cm. long.
(Note: The above items are available from PEL Supply Company, 4666 Manufacturing Road, Cleveland, Ohio 44135.)
8. One set E.P.P.O. connector wires.
9. Battery pack for E.P.P.O.
(Note: The above items are available from Orthotic Systems, Inc., P.O. Box 20262, Houston, Texas 77025.)
10. One plastic pipette tip (available through many surgical supply houses).
11. Experimenter Box, CAT #270-232 (available at many Radio Shack stores).
12. Two $\frac{4}{40}$ machine screws 1" long with nuts attached.

The assembly of the B.A.S.M./E.P.P.O. is shown in Illustrations A-M. Item numbers in instructions refer to items in the above list.

The B.A.S.M. can easily be adapted for use with any externally powered orthosis or prosthesis that operates on a 6-volt system. It can be adapted to operate a 12-volt system by substituting 12-volt relays and integrated circuits.

**PRECAUTIONS**

A few precautions must be taken by users of the B.A.S.M. The B.A.S.M. will not operate properly if the pressure introduced through the air hose to the sensors is not expelled. Expelling the air volume is easily accomplished by:

1. Removing the tube from the mouth; or
2. Removing the tube from the "T" connector.

Care must be taken to eliminate saliva and food particles from the tube to prevent its interfering with open parts of the sensors which must not be blocked. Special attention must be given to this precaution when the B.A.S.M./E.P.P.O. is used for eating activities. Simple, common sense
practices such as swallowing drinks, food, or saliva prior to activation of the switch should protect the switch and should not interfere with activities.

RESULTS

Although formalized clinical evaluation using an evaluation protocol which we have developed is still underway, informal observations reveal a clear superiority of the B.A.S.M. over other switching mechanisms we have tried for the E.P.P.O. The B.A.S.M./E.P.P.O., by offering the patient some direct use of his hands,
Figure 12-G. Place Item #9 in Item #11, mark location of battery charger plug and battery connector wire plug.

Figure 12-H. Use a 3/8" H.S. drill to drill a hole for plugs.

Figure 12-I. Attach Item #9 to Item #11 by drilling a 1/8" hole as shown and inserting item #12.

Figure 12-J. Place the B.A.S.M. into Item #11, locate the position for the 5/32" transparent tube, mark and drill with a 9/32" H.S. drill.

Figure 12-K. Replace the bottom to Item #11, attach the arm band to the transparent tube and orthosis wire connector as shown.
Figure 12-L. The assembled B.A.S.M./E.P.P.O.

seems to encourage the patient’s participation in strengthening functions (e.g., shoulder and elbow movement) that have been spared.

The B.A.S.M. is much easier for patients to learn to use than are the other switching mechanisms. Although rehabilitative training is still important to assure optimal function and acceptance,\(^5,6\) most of our patients have been able to operate the orthosis without difficulty after only one training session. The ease of use seems to encourage patients to try new tasks on their own with their new orthosis, for example, eating fragile finger foods such as potato chips or sandwiches.

One of the primary objectives has been to reduce the need for attendant care. It remains to be formally determined whether this objective can be achieved to a sufficient extent that it will improve the patient’s abilities to attend school or engage in gainful employment. However, our patients agree that their need to request help from others has been reduced.

CONCLUSIONS

A B.A.S.M. can be simply and economically adapted for use with the E.P.P.O. to provide quadriplegic persons with easily controlled finger prehension. Operation of the B.A.S.M. does not require the muscle effort, proprioception, use of contralateral limbs or extensive training that are necessary for the use of other switching systems available for E.P.P.O. use. Therefore, the B.A.S.M. should be a useful tool to provide early restoration of independent function to certain quadriplegic persons.

AUTHORS

Virgil W. Faulkner, C.P.O., is Director of the Rehabilitation Engineering Laboratory as well as Assistant Professor in the Department of Physical Medicine and Rehabilitation at the University of Texas Health Science Center at San Antonio. He is a graduate of the State University of New York, Albany and has been with the University of Texas Health Science Center at San Antonio since 1982. He has published extensively, and is an active member of the American Academy of Orthotists and Prosthetists, is involved with the American Orthotic and Prosthetic Association, and is certified by the American Board for Certification in Orthotics and Prosthetics. Mr. Faulkner is on the Advisory Board of Rehabilitation Engineering Centre at the University of Texas at Arlington. His professional interests include aramid and carbon fibers, prehension devices, and breath activated switching mechanisms.

Debbie Keene, O.T.R., is a Staff Therapist and Clinical Coordinator at Villa Rosa Medical Center. She is a 1982 graduate of the University of Texas Health Science Center at San Antonio and is currently in the Army Reserve working at the Institute of Surgical Research-Burn Ward, Ft. Sam Houston, Texas. She is an active member of the American Occupational Therapy Association and of the Texas Occupational Therapy Association. Her professional interests include spinal injury and closed head injuries.

Richard N. Friedman, M.D, is a Research Assistant Professor in the Physiology Department at the University of Texas Health Science Center at San Antonio since 1981, and is an adjunct Assistant Professor in the Department of Zoology at the University of Texas at Austin. He received his degree in physiology at Temple University School of Medicine, Philadelphia, Pennsylvania and his postdoctoral training at the Hadassah Medical School Hebrew University of Jerusalem. He was a Research Assistant in the Department of Neurology at Stanford University School of Medicine with his primary field being in neurophysiology. His primary interests are in neuromuscular junction and synaptic transmissions.

Donald M. Currie, M.D., is an Associate Professor of Physical Medicine and Rehabilitation, Pediatrics, Physical Therapy, and Occupational Therapy at the University of Texas Health Science Center at San Antonio. Dr. Currie received his medical degree from the University of Texas Southwestern Medical School in Dallas and completed his residency in Physical Medicine and Rehabilitation at the University of Washington School of Medicine. His professional interests include pediatric rehabilitation, functional adaptive equipment for high quadriplegic patients, and seating and mobility aids for severely paralyzed patients.
